Carboxylic Acids¹ and Derivatives

GF of monocarboxylic acids: RCO_2H , if aliphatic- $C_nH_{2n}O_2$

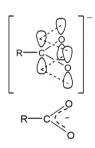

Physical Properties:

- Liquid/ solid at rtp
- Boiling point increases as no of C atoms increases
 → strength of id-id i between R groups increases
- Have higher boiling point compared to alcohol of similar Mr
 → more sites for formation of hb → more extensive hb
 → stronger hb
 → O-H bond in -COOH more polar due to the presence of electron withdrawing carbonyl group²
- Solubility in water decreases, solubility in non-polar solvents increases as length of non-polar hydrocarbon chain increases
 Benzoic acid dissolves readily in hot water but is only slightly soluble in cold water. White ppt of benzoic acid appears when the hot solution is cooled
- Can form dimers through hb formation between 2 molecules

Acid Strength:

Depends on stability of anion formed

$$RCOOH(aq) \rightleftharpoons H^+(aq) + RCOO^-(aq)$$

Explanation:

- 1. Order of acid strength
- 2. Electron donating/ withdrawing effect
- 3. Effect (intensify/ disperse) negative charge on $-COO^-$ group
- 4. Stability of anion

E.g. Electronegativity and electron withdrawing effect increases from I to Br to Cl to F. F being the <u>most electronegative and the most electron withdrawing</u>, it disperses the negative charge on $-COO^-$ group on <u>most effectively</u> among the 4 halogen atoms. CH_2FCOO^- is the most stable anion followed by CH_2ClCOO^- , CH_2BrCOO^- , CH_2ICOO^- . Hence, H_2FCOOH is the most acidic followed by $CH_2ClCOOH$, $CH_2BrCOOH$, CH_2ICOOH .

Negative charge on $-COO^-$ group is dispersed **most effectively**, with <u>more</u> electronegative halogen and <u>proximity of</u> electron withdrawing group with the $-COO^-$ group.

Note: Benzoic acid is stronger than some aliphatic acids due to delocalisation ³ of negative charges of benzoate anion into the benzene ring \rightarrow benzoate anion more stable than some carboxylate anion

Acid strength: ethanol < water < phenol < carboxylic acids < mineral acids

¹ Example: CA: Propanoic acid, Salt: propanoate

² Due to greater electron deficiency of H atom of -OH group, resulting in stronger attractive force between electron deficient H atom and lone pair of e on another molecule

 $^{^3}$ condition: overlap of orbitals. \neq dispersion, where the condition is attractive force of an electron withdrawing atom

Preparation:

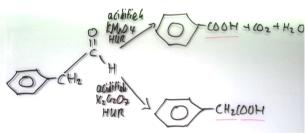

1. **Oxidation** of primary alcohols and aldehydes (Hydroxyl Compounds)

R/C: Acidified $KMnO_4$ or acidified $K_2Cr_2O_7$, HUR

2. Oxidation of alkyl benzenes (Arenes)

R/C: Acidified KMnO₄, HUR

For 1 and 2, when reactant has a BR, using acidified $KMnO_4$ or acidified $K_2Cr_2O_7$ will affect the type of product formed.

It is easier to oxidize primary alcohol than an alkyl group on BR side chain.

3. **Oxidation** of alkenes with structure $\underline{\mathsf{RCH=CHR'}}$ (Alkenes) Involve cleavage of C=C R/C: Acidified $KMnO_4$, HUR Example:

Hydrolysis of nitriles (Halogen Derivatives)
 R/C:

1 Acidic Hydrolysis: Dilute HCl (aq)/ H_2SO_4 (aq), HUR

② Alkaline Hydrolysis + Acidification: NaOH (aq), HUR, followed by dilute HCl (aq)/ H_2SO_4 (aq)

5. Hydrolysis of acyl chlorides and esters

$$R-C$$
 Cl
+ H_2O
 $R-C$
 OH
+ HCl

$$R-C$$
 + H_2O + $H_2SO_4(aq)$ $R-C$ + R'OH heat under reflux

Reactions:

Electron deficient carboxyl carbon is <u>susceptible to attack by nphile</u>, but <u>less susceptible to attack by nphile</u> as compared to carbonyl carbons of ketones and aldehydes

Lone pair in p orbital of O atom of -OH group can be **delocalised** into π bond of -C=O group \rightarrow **drift of electron density** from O atom of -OH group towards the electron deficient carbon \rightarrow **reduce the partial positive charge** on carboxyl carbon

Reactions involving cleavage of O-H bond:

1. Reaction with reactive metal

RCOOH + Na
$$\longrightarrow$$
 RCOO $^-$ Na $^+$ + $\frac{1}{2}$ H₂

2. Reaction with bases

RCOOH + NaOH
$$\longrightarrow$$
 RCOO $^{-}$ Na $^{+}$ + H₂O

3. Reaction with CO_3^{2-} or $HCO_3^ 2RCOOH + Na_2CO_3 \longrightarrow 2RCOO^-Na^+ + CO_2 + H_2O$

RCOOH + NaHCO₃
$$\longrightarrow$$
 RCOO $^-$ Na $^+$ + CO₂ + H₂O

Allows for carboxylic acids to be distinguished from phenols and alcohols.

Observation: $CO_2(g)$ evolves forms white ppt with limewater.

As mineral acids are stronger than carboxylic acid, addition of mineral acid converts the salt of carboxylic acid back to the original acid.

N.B. Carboxylic only exhibit acidic property in aq medium. Reactions 2 and 3 occurs only in aqueous medium. But reaction 1 may still happen in non-aqueous mediums.

Reactions involving cleavage of C-O bond:

4. **Condensation** reaction to form ester (Hydroxyl Compounds) R/C: Alcohol, a few drops of con H_2SO_4 , HUR Purpose of con H_2SO_4 : **Catalyst** to protonate carboxylic acid, **dehydrating agent** to remove water and favour fwd rxn

Take note of the bonds cleaved to form ester

5. **Condensation** reaction to form acid anhydride from 2 carboxylic acids

6. **Nucleophilic substitution** to form acyl chlorides R/C: PCl_5 or PCl_3 or $SOCl_2$, room temperature

RCOOH + PC
$$I_5$$
 \longrightarrow RCOC I + POC I_3 + HC I_3 \longrightarrow 3RCOC I + H₃PO₃

RCOOH + SOC I_2 \longrightarrow RCOC I + SO₂ + HC I

<u>HCOOH does not form acyl chloride</u>. This is because HCOCl is highly unstable and decomposes to give CO and HCl.

Others:

7. **Reduction** of carboxylic acid R/C: $LiAlH_4$ in dry ether only

RCOOH +
$$4[H] \xrightarrow{\text{LiA/H}_4} \text{RCH}_2\text{OH} + \text{H}_2\text{O}$$

1° alcohol

If $NaBH_4$ is used, it will allow for selective reduction.

- 8. Special Cases: Methanoic Acid and Ethanedioic Acid
 - a. Oxidation by acidified $KMnO_4$

HCOOH + [O]
$$\frac{\text{acidified KMnO}_4}{\text{heat under reflux}} CO_2 + H_2O$$

H

(COOH)₂ + [O] $\frac{\text{acidified KMnO}_4}{\text{heat under reflux}} 2CO_2 + H_2O$

H

O

H

O

H

b. Methanoic Acid is able to give <u>false +ve test with</u> <u>Fehling's reagent and Tollen's reagent</u>, as it has an aldehyde group and is easily oxidised.

Carboxylic Derivatives:

Derivatives	Nomenclature	Physical properties		
Acyl	ethan oic acid	Boiling point lower than		
chlorides	to ethan <u>oyl</u>	carboxylic and alcohols of		
	<u>chloride</u>	comparable Mr.		
Esters	ethyl (alkyl group	→ pd-pd i between molecules		
	attached to O)			
	ethan <u>oate</u>	Acyl chlorides soluble in water.		
	(carboxylic acid	Esters slightly soluble (up to 5C).		
	portion)			
		Esters are isomeric with carboxylic acids.		
Amides	3-bromobenz oic	Boiling point higher than		
	acid to 3-	carboxylic and alcohols of		
	bromobenz <u>amide</u>	comparable Mr.		
		Fairly soluble in water.		
		→ hb between molecules		
		All are white crystalline solid at trp		
		except methanamide (I).		
Acid	Ethanoic			
anhydride	propanoic (name			
	of acid w/o 'acid')			
	anhydride			
	If 2 acids are the			
	same, e.g.			
	ethanoic			
	anhydride.			

Reactions:

Acyl chlorides

1. Hydrolysis/ Nucleophilic Substitution (Vigorous rxn)

$$R-C \stackrel{O}{\downarrow} + H \stackrel{O}{\downarrow} + H-Cl$$

Observation: Moist blue litmus paper turns red. When $AgNO_3$ (aq) is added to resulting soliton, white ppt of AgCl is formed immediately.

Distinguishing test for acyl chlorides

N.B. <u>Benzoyl chloride is less reactive than alkyl acyl chlorides</u>. Reason: Delocalisation of electron density between p orbital of Cl atom, π bond in C=O group and π electron cloud of BR \rightarrow reduce partial positive charge on carbonyl carbon

Ease of hydrolysis	RCOCl >	$RCH_2Cl >$	C ₆ H ₅ Cl
R/C	H_2O , room temp	NaOH (aq), heat	No rxn
Reason	Carbonyl carbon in - COCl is highly electron deficient, as it is bonded to 2 electronegative atoms, hence easily attacked by nucloephiles	Carbon atom of C- Cl less electron deficient than in RCOCI	Stronger C-Cl bond with partial double bond character

2. Condensation reaction to form ester (Hydroxyl Compounds)

$$R-C$$
 O
 CI
 $+$
 $R'CH_2O-H$
 $temp$
 $R-C$
 $O-CH_2R'$
 $+$
 HCI

3. Condensation reaction to form amide

$$R-C = \begin{pmatrix} 0 \\ + NH_3 \\ - R-C \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ + R'NH_2 \\ 1^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ - I \\ 1^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ + (R')_2NH \\ - I \\ 2^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ - I \\ 2^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ - I \\ 2^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ - I \\ 2^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ - I \\ 2^0 \text{ amine} \end{pmatrix} + HCI$$

$$R-C = \begin{pmatrix} 0 \\ - I \\ 2^0 \text{ amine} \end{pmatrix} + HCI$$

Ester (reversing formation of ester)

1. Acidic Hydrolysis R/C: Dilute HCl(aq) or $H_2SO_4(aq)$, HUR $R = C + H_2O + H_2O + H_2SO_4(aq) + R + R'OH$ 1. Acidic Hydrolysis R/C: Dilute HCl(aq) or $H_2SO_4(aq)$ and HCl(aq) or $H_2SO_4(aq)$ and HCl(aq) or $H_2SO_4(aq)$ and HCl(aq) or $H_2SO_4(aq)$ and HCl(aq) and HCl(aq)
